

An eBay selling engine run by AI agents

Scans physical cards, identifies and prices them,
lists them, and optimizes the catalog daily.

Built and operated by one person, with a multi-agent assistant.

CORE PIPELINE

Scan to listing, no manual data entry

1. Scan

Nine cards per flatbed scan (a 3×3 grid).

2. Grid split

Auto-cut into 9 images, snapping to the gaps so die-cuts aren't clipped.

3. Identify — agents

One agent per scan reads the images, returns year/brand/parallel/player/price as data. 17 scans

4. Dedup guard

Checks active + 90-day sold + within-batch. A 1-of-1 can never list twice.

5. Price

SportsCardsPro-anchored, confidence-gated; autos & rare parallels get a deep-dive.

6. Post

eBay Trading API, image upload, returns-not-accepted, dupe-checked at post time.

The morning routine

~25 agents run each morning. Every one produces a plan and a dashboard first; live actions are applied only after review.

Repricing

Toward market, capped per run — trends down to move stock.

Markdowns

Age-tiered, floor-protected so nothing sells below its floor.

Promoted listings

Per-listing ad bids — the visibility lever.

Offers to watchers

Targeted discounts to the highest-intent buyers.

Best Offer

Re-clamps thresholds so a price drop never breaks a rule.

Health & digests

Inventory, photo audit, Cassini scoring, daily digest.

More than a script

Sourcing committee

A panel of agent personas debates which players to buy next.

3-card lots

An expert committee bundles slow singles into themed lots, priced to move.

Premium deep-dive

Autos & rare parallels are verified and comp-priced individually.

Self-auditing review

Code changes reviewed by a 9-angle agent fan-out; each bug verified before fixing.

QC review page

Every posted card re-checked against its image with a confidence score.

Analytics

Titles parsed into fields for filterable insight on what's selling.

Fan out, verify, synthesize

Fan-out

160 cards or 9 review angles run as parallel agents — wall-clock is the slowest one, not the sum.

Structured output

Agents return validated JSON (titles, prices, verdicts) that drops straight into the pipeline.

Adversarial verification

Findings and IDs are confirmed by separate agents — how mis-IDs get filtered out.

Committees

For judgment calls, agents argue distinct positions and a chair synthesizes the decision.

BUILT ON

One repo, one operator

The only manual steps are scanning cards and approving the actions that touch live listings. Everything else is agents.
